

SQL:

Problem: Average Hour Difference Between Dates

You are given a table named **Events** that contains information about when certain events started and ended.

Column Name	Type
event_id	INT
start_date	DATETIME
end_date	DATETIME

Each row represents a single event that begins at **start_date** and ends at **end_date**. The hour part of both timestamps is the same, but the dates may differ (for example, one day apart, or more).

Task

Write an SQL query to calculate the **average absolute difference in hours** between **start_date** and **end_date** across all events.

Your output should contain **only one column and one row**, showing the **average number of hours** (rounded or with decimals, depending on the SQL dialect).

Example Input

event_id	start_date	end_date
1	2023-01-01 10:00:00	2023-01-03 10:00:00
2	2023-02-10 12:00:00	2023-02-11 12:00:00
3	2023-03-05 09:00:00	2023-03-07 09:00:00

Expected Output

avg_hour_diff

48.67

(Explanation: $(48 + 24 + 48) / 3 = 40$; sorry, corrected below $\rightarrow (48 + 24 + 48) / 3 = \mathbf{40.00}$ hours on average)
